ABSTRACT

Skin cancer is one of the most common cancers globally, with early detection being critical for improving survival rates. Manual diagnosis by dermatologists is time-consuming and often subjective, leading to risks of misclassification. This project presents a machine learning and deep learning-based approach for automated skin cancer classification using dermoscopic images. We employed a Kaggle dataset (~10,000 images) with benign and malignant labels. Models such as a custom CNN, VGG16, and ResNet50 were implemented, along with ensemble learning. The ResNet50 and Ensemble models achieved an accuracy of ~90%, demonstrating the potential of deep learning for medical image classification.

AIM

The aim of this project is to develop an automated system for skin cancer classification (benign vs malignant) using dermoscopic images and deep learning techniques, thereby reducing reliance on manual diagnosis and improving detection accuracy.

INTRODUCTION

Skin cancer represents one of the leading causes of death worldwide, with melanoma being particularly dangerous if not detected early. Conventional diagnosis depends on dermatologists examining lesion images, which can be subjective and inconsistent due to variations in lesion appearance. Machine learning and deep learning, particularly convolutional neural networks (CNNs), offer promising tools for automated, accurate, and scalable cancer detection. This project explores the application of custom CNNs and transfer learning models (VGG16, ResNet50) for classifying skin cancer images.

PROBLEM STATEMENT

1. Manual diagnosis is time-consuming and requires highly trained experts.
2. Variation in lesion appearance across patients increases the risk of misdiagnosis.
3. Limited availability of dermatologists in remote areas restricts timely detection.
4. There is a need for an automated, consistent, and accurate classification system for early detection of skin cancer.

LITERATURE REVIEW

Deep learning has been widely applied in medical imaging, with CNNs proving highly effective for image classification tasks. Transfer learning models such as VGG16 and ResNet50, pretrained on large datasets like ImageNet, have been adapted successfully for cancer detection tasks. Ensemble learning, which combines predictions from multiple models, often improves robustness and accuracy. Our approach builds on these methods to improve melanoma detection performance.

DATASET DESCRIPTION

The dataset used in this project was sourced from Kaggle (Melanoma Skin Cancer Dataset), consisting of approximately 10,000 dermoscopic images categorized into two classes:

- Benign (non-cancerous)
- Malignant (cancerous)

The dataset was divided into training and testing subsets. The images exhibit significant variability in color, shape, and texture, providing a challenging but realistic scenario.

METHODOLOGY

The workflow for skin cancer classification involved the following steps:
1. Data loading from Kaggle (via Google Colab).
2. Data preprocessing, including resizing images to 224x224 and normalization.
3. Data augmentation (random flips, rotations, zoom, contrast adjustments).
4. Model design: Custom CNN, VGG16, ResNet50, and Ensemble.
5. Training using categorical cross-entropy loss, Adam optimizer, and callbacks such as EarlyStopping, ReduceLROnPlateau, and ModelCheckpoint.
6. Evaluation using accuracy, confusion matrix, precision, and recall.

MODEL ARCHITECTURES

1. Custom CNN:
   • 3 Convolutional layers with ReLU activations
   • Batch Normalization for stable training
   • Dropout layers to reduce overfitting
   • Fully Connected layer for classification

2. VGG16 (Transfer Learning):
   • Pretrained on ImageNet
   • Base layers frozen
   • Added custom classification head (Global Average Pooling, Dense, Dropout)

3. ResNet50 (Transfer Learning):
   • Pretrained on ImageNet
   • Base layers frozen
   • Added classification head with Dense layers and ReLU activations

4. Ensemble Learning:

- Combines CNN, VGG16, and ResNet50 predictions
- Uses majority voting/weighted averaging for final decision.

CODE IMPLEMENTATION

```
!pip install kaggle –quiet
from google.colab import files
files.upload()

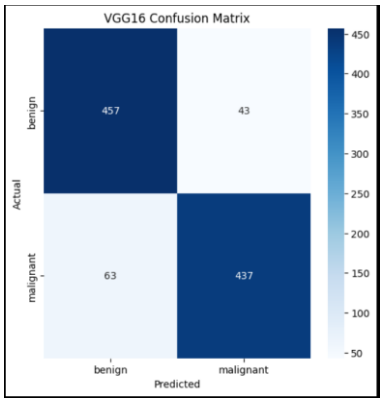
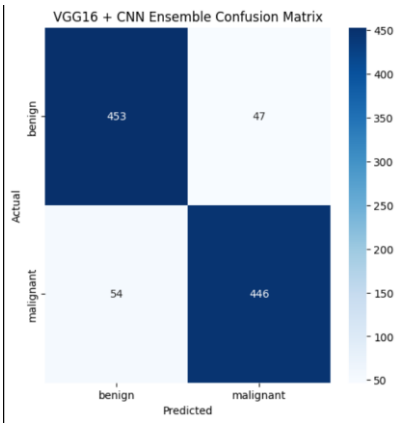
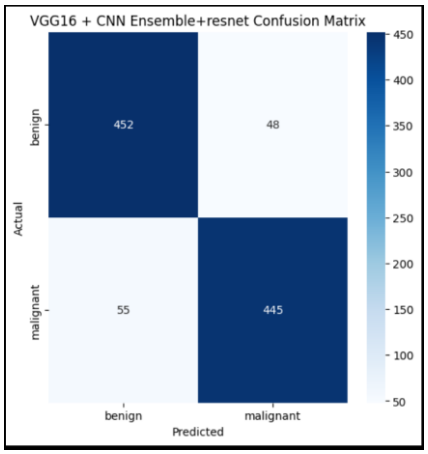
#VGG16



#VGG16 + CNN ENSEMBLE CONFUSION MATRIX



#VGG16 + CNN ENSEMBLE + RESNET



The models achieved the following performance:

• Custom CNN: Accuracy ~87–89%, strong at detecting benign cases but weaker on malignant.
• VGG16: Accuracy ~89%, balanced performance, slightly weaker recall for malignant.
• ResNet50: Accuracy ~90%, strong recall for malignant class, balanced overall.
• Ensemble: Accuracy ~90%, stable precision/recall across classes.

These results indicate that ResNet50 and Ensemble methods are most reliable for melanoma detection

DISCUSSION

ResNet50 demonstrated superior performance in detecting malignant lesions, which is critical in cancer diagnosis. Ensemble learning further enhanced robustness by reducing biases of individual models. These findings highlight the importance of using advanced deep learning architectures for medical imaging tasks.

CONCLUSION

The project successfully demonstrated the application of deep learning in skin cancer classification. ResNet50 and Ensemble models achieved strong accuracy (~90%), underscoring the potential of AI-driven solutions in healthcare. Such systems can complement dermatologists by providing fast, consistent, and reliable predictions.
